Pattern Validation Types

Veritas Pattern validation types:

- **none:** No particular validation is performed in the matching logic. The pattern may still employ corroborative evidence.
- **heuristic:** The matching logic uses one or more heuristics for validation. Heuristics are typically restrictions in the matching logic, and do not involve mathematical computation as part of the matching logic. Most of Veritas's Patterns use heuristics to validate the matches. Employing heuristics in the matching logic reduces the number of false positives.

Unless otherwise specified in the pattern pack, Veritas patterns use heuristic validation by default. An example of a heuristic is matching a 10-digit number which only begins with the digits 1 - 4.

Another example is to validate that a sequence of 8 digits of the form YYYYMMDD presents a valid date (for example, the days presented by DD is within range for the specified month).

- **checksum:** The matching logic employs a mathematical calculation to compute and verify one or more digits or letters, along with heuristics. Checksum validations are performed by purpose-built code functions; they cannot be achieved using regular expressions. Checksums generally provide stronger validation—and therefore even fewer false positives—than heuristics alone.

Examples of a checksum is Luhn's algorithm and modulus calculations (mod 10, mod 13, etc).

- **discrete:** The matching logic restricts the possible values to the specific set of values that are valid for the data element. The set of discrete values are typically exported from the source of all values, such as a database for example. Discrete data sets typically have few—if any—false positives.

An example of discrete validation is the complete set of patient ID numbers.
